### **III. Realizare remarcabilă**

(Descrieți într-o manieră cât mai accesibilă (în maximum 1 pagină) cea mai importantă realizare științifică/tehnică/artistică din ultimii 5 ani și impactul acesteia.)

Dezvoltarea unor metode chemometrice robuste privind determinarea unor noi scari de lipofilicitate prin cromatografia de lichide de înaltă performanță, folosind plăci de silicagel chimic legate, plăci impregnate (ulei de parafină, uleiuri minerale, grasimi animale, inclusiv grasime umană) și amestecuri metanol-apa ca fază mobilă, a unor clase de compuși de interes deosebit (medicamente, aditivi alimentari, îndulcitori naturali și sintetici, pesticide și clase noi de compuși potențial biologic activi). Aceste materiale (faze staționare inverse) constituie modele potrivite pentru simularea barierelor lipofile pe care o substanță, ce prezintă activitate biologică, trebuie să le străbată pentru a ajunge la celula țintă. Valorile recomandate în literatura de specialitate, obținute prin analiza de regresie liniară clasică pe baza datelor de retenție cromatografică, au fost comparate cu valorile obținute aplicând pentru prima dată statistica rangurilor, precum și cu scorurile obținute prin aplicarea analizei componentelor principale (PCA) la aceleași date cromatografice. Relevanța valorilor obținute prin metoda rangurilor, precum și a scorurilor obținute de-a lungul primei componente principale, ca noi indici de lipofilicitate, a fost validată prin studii comparative cu valorile experimentale obținute prin metoda clasică, precum și cu diferiți descriptori moleculari (topologici, geometrici, electrostatici, cuantici etc.) calculați cu programe complexe. Corelarea semnificativă a rezultatelor cromatografice cu datele calculate prin metode computaționale moderne a permis elaborarea unor modele predictive semnificative din punct de vedere statistic privind activitatea biologică sau toxicitatea compusilor chimici indiferent de structura chimică a acestora. În plus, scorurile după prima componentă principală obținute cu ajutorul analizei componentelor principale pot constitui un suport mult mai obiectiv pentru scara de lipofilicitate. De asemenea, s-au definit noi scari de lipofilicitate bazate pe statistica rangurilor și s-a folosit cu succes metoda PCA în studiile de tipul structură-activitate pentru diverse clase de compuși. Mai mult, harta de lipofilicitate descrisă de primele două componente principale, precum și spațiul de lipofilicitate descris de primele trei componente principale au avut ca un prim efect separarea efectivă a compusilor, din punctul de vedere al activității biologice, în grupuri congenerice bine delimitate. Pe baza rezultatelor experimentale obținute, se poate aprecia că plăcile chimic legate, precum și plăcile impregnate cu diferite uleiuri minerale și grasimi animale constituie suporturi (modele) foarte potrivite pentru simularea barierelor hidrofobe pe care o substanță, ce prezintă activitate biologică, trebuie să le străbată pentru a ajunge la celula țintă. În plus, mediile și rangurile marimilor de retenție și mai ales scorurile după prima componentă principală, obținute cu ajutorul analizei componentelor principale, pot constitui un suport mult mai obiectiv pentru scara de lipofilicitate. Rezultatele obținute au fost validate prin lucrări științifice publicate în reviste internaționale prestigioase și prin numărul de citări ale articolelor respective.
